5TH INTERNATIONAL
CONFERENCE
12 – 14 JUNE 2019
SOPHIA ANTIPOLIS - FRANCE

A framework to design a municipal decision support tool for cyclone-induced marine flooding emergency management at Reunion Island

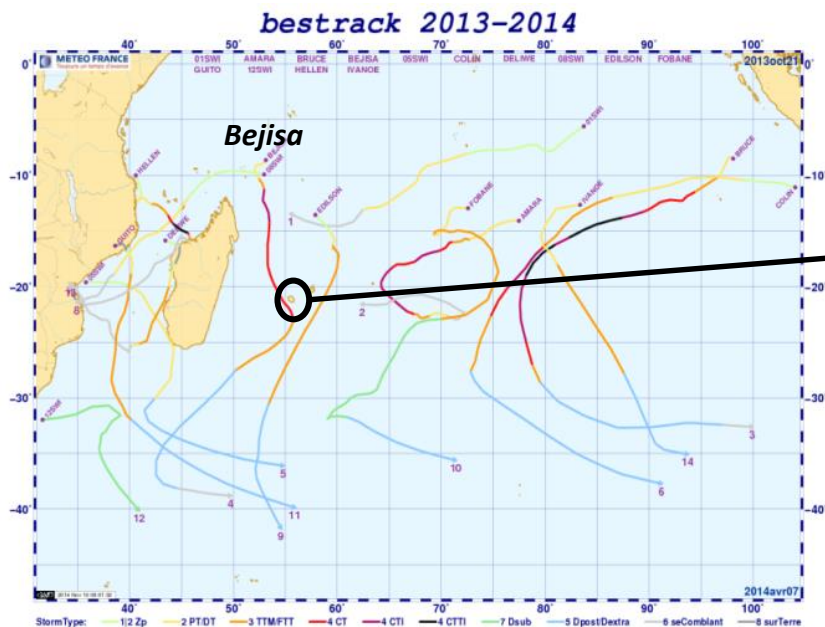

François Paris, Sophie Lecacheux, Rodrigo Pedreros, Jérémy Rohmer (BRGM, Orléans)

Sophie Sauvagnargues, Pierre-Alain Ayral, Florian Tena-Chollet (Mines d'Alès)

François Bonnardot, Hubert Quetelard (Météo-France, La Réunion)

- The most exposed among the French Overseas Territories
 - 23 cyclones passed within 200km of the island over the last 30 years
- ... but no marine flooding forecast system so far

High uncertainties due to the track forecast errors !

Cyclone Bejisa (2014)

- > Situated on the Northern coast of the island (the most exposed)
- > Marine flooding due to wave overtopping only (no overflowing)

- The municipal services don't know how to interpret marine forecasts into flooding impact
- They can't anticipate and organize their operational response

- Situated on the Northern coast of the island (the most exposed)
- Marine flooding due to wave overtopping only (no overflowing)

- The municipal services don't know how to interpret marine forecasts into flooding impact
- They can't anticipate and organize their operational response

Produce a pragmatic tool linking the weather and marine forecasts with potential impacts on land and appropriate operational responses.

But

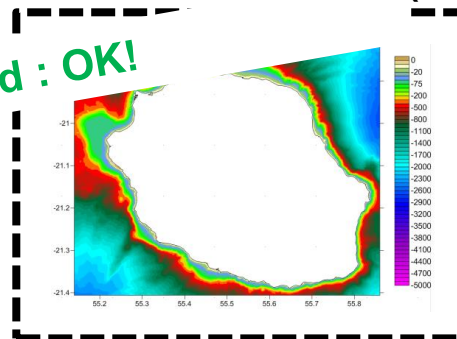

- > Need to have a “**easy to use**” tool for non-experts users
- > Scarcity of **historical events** (in recent years)
- > The **high computation time** to simulate marine flooding by overtopping hampers the implementation of operational forecast systems

CHAIN OF MODELS USED BY BRGM

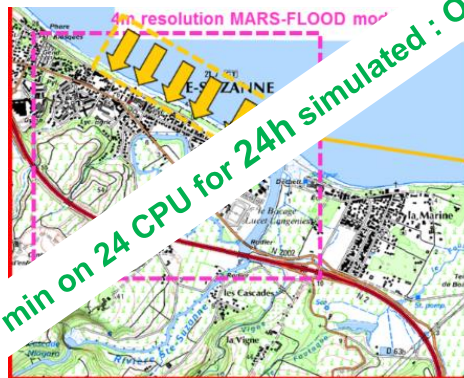

WAVES : Wavewatch 3 (10km => 300m)

WATER LEVEL : MARS (100m)

INUNDATION : MARS FLOOD (1m resolution MARS-FLOOD model)

VERTOPPING : SWASH profiles (Non-hydrostatic model)

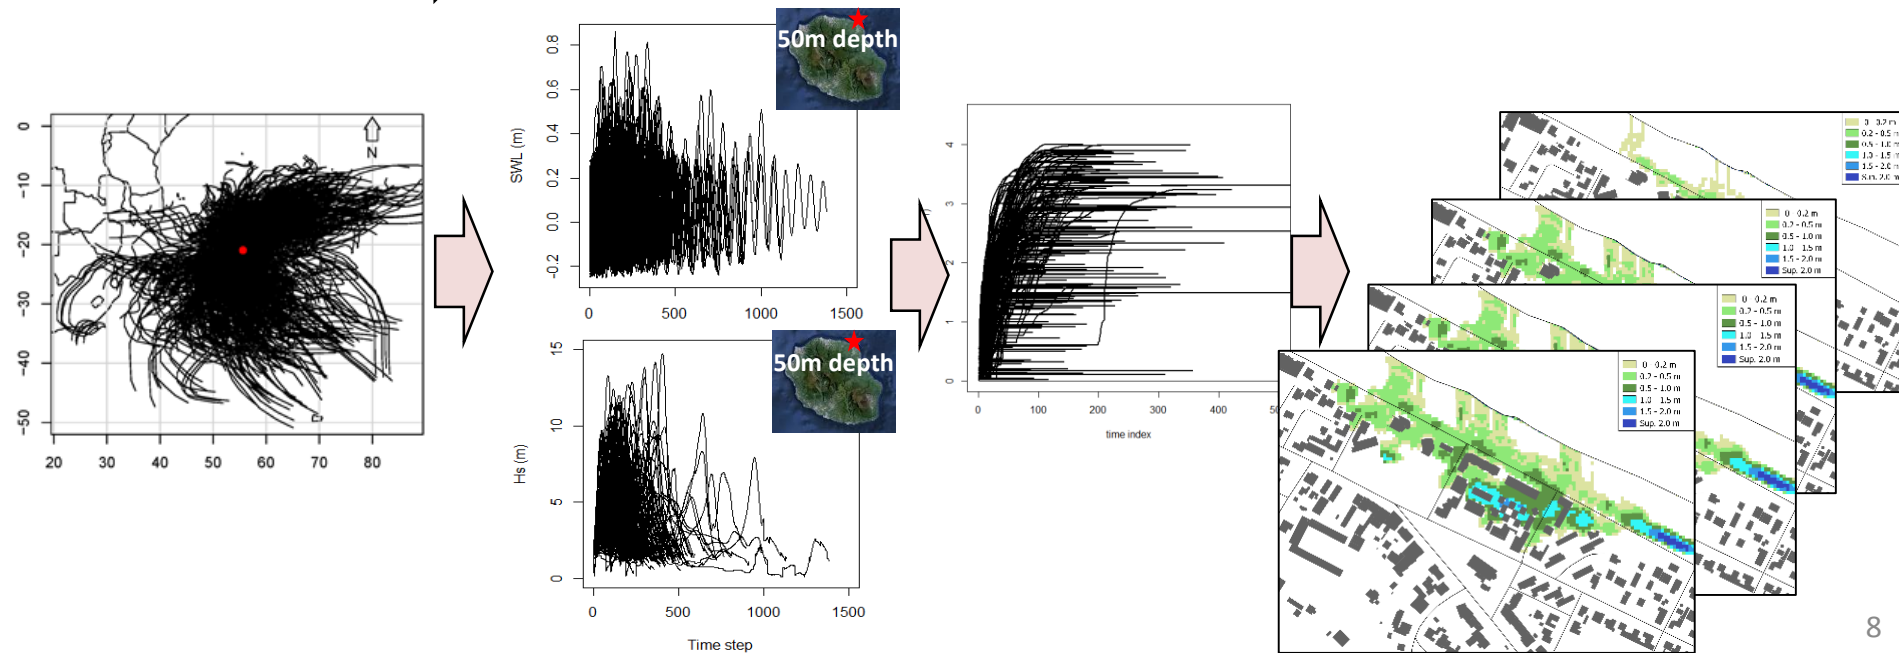

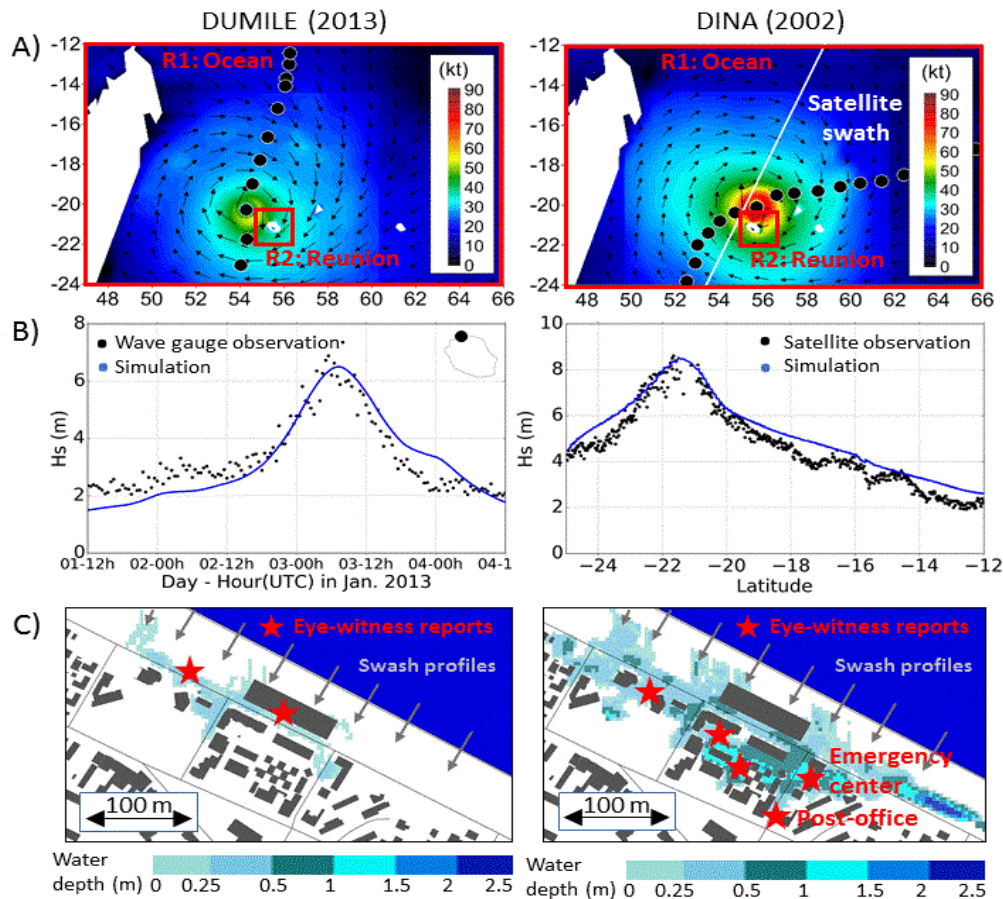

Produce a pragmatic tool linking the weather and marine forecasts with potential impacts on land and appropriate operational responses.

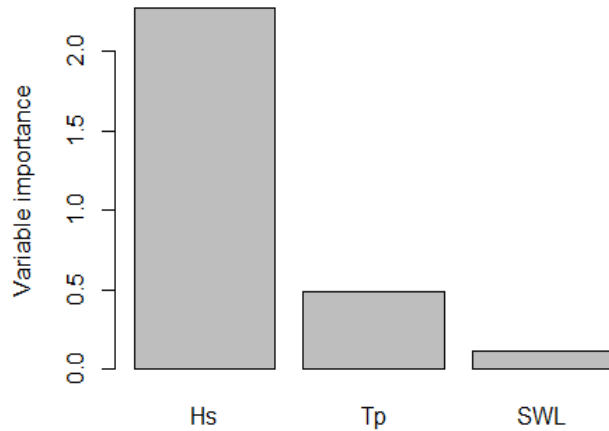

Solution proposed here

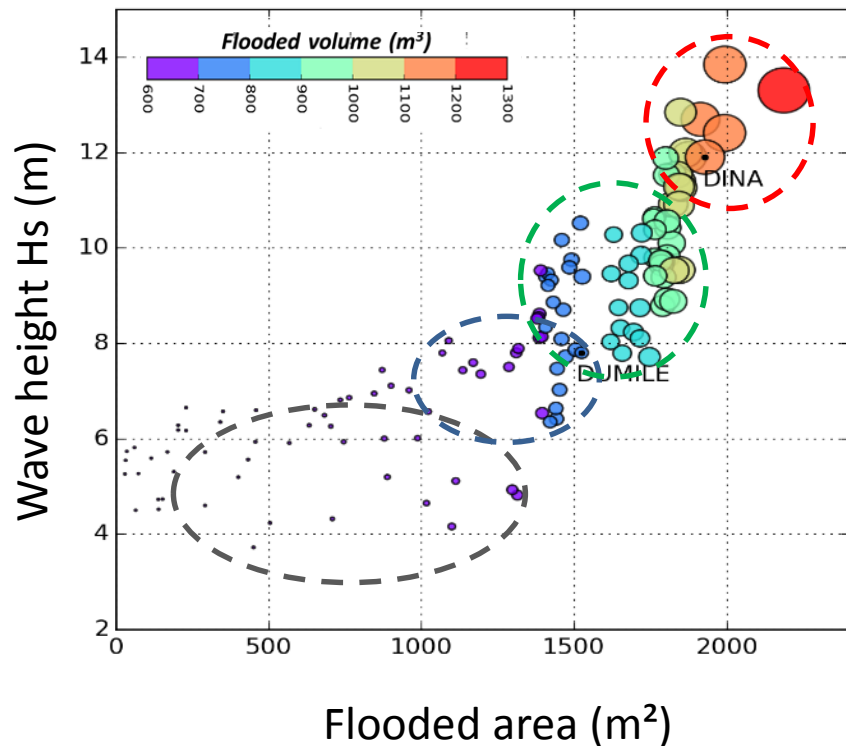

- > Construct **Graduated Intervention Plans (GIP)** = series of maps representing the extent of potentially impacted areas, structured in gravity levels regarding the marine conditions
- > Based on **feedback** analysis, **field** observations and state-of-the-art hydrodynamic **modelling**
- > Use of the complete chain of models to build a **pre-calculated synthetic but realistic marine flooding database**

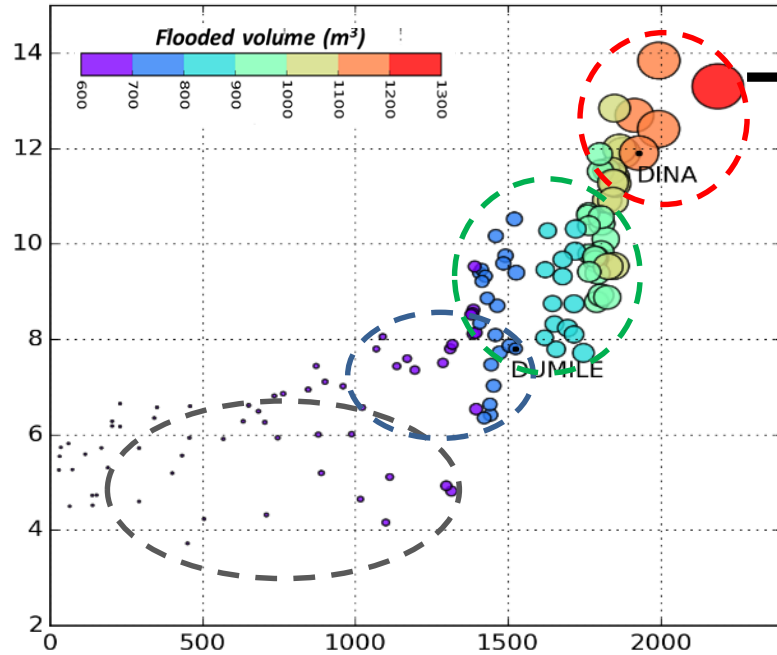

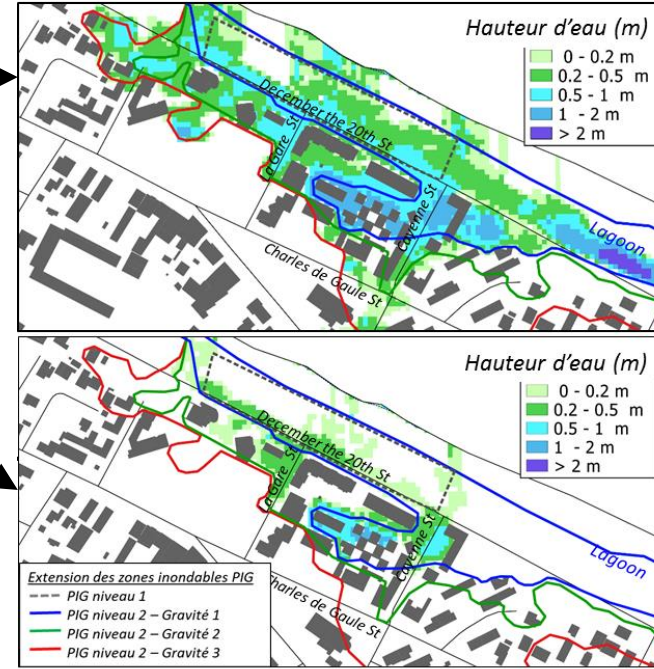

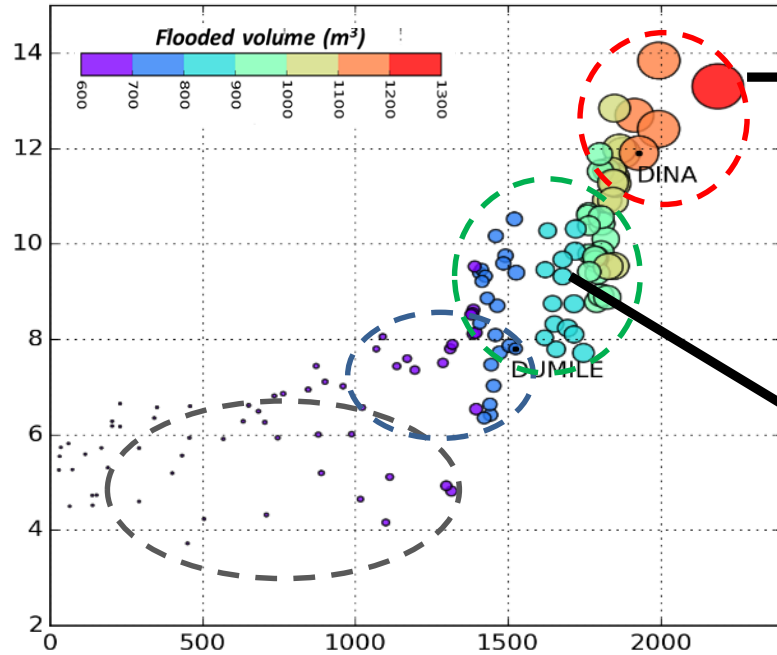

- > Marine flooding is governed by **multiple parameters** (waves, tide and storm surge)
- > Analysis of the relative importance of waves and water levels with the respect to the overtopping volume (**Classification Random Forest – see this afternoon presentation ;-)**)
- > The wave height (H_s) = **main parameter controlling the discharge volume**

- > **Collaboration with the municipal services** to transpose the flooding maps into a Graduated Intervention Plan (GIP) :
- Determination of the **number of levels** to consider
 - Adaptation of the **boundaries of the maps** to fit with the particularities of the territory
 - Determination of **specific actions** to conduct for each level: monitoring points, road closure points, circuit of the sound car (mobile warning system), etc.

- > **Collaboration with the municipal services** to transpose the flooding maps into a Graduated Intervention Plan (GIP) :
 - Determination of the **number of levels** to consider
 - Adaptation of the **boundaries of the maps** to fit with the particularities of the territory
 - Determination of **specific actions** to conduct for each level: monitoring points, road closure points, circuit of the sound car (mobile warning system), etc.

 - > The **transition conditions** between the different levels rely on :
 - 1) Direct observations of the consequences on the field (**current practice**)
 - 2) **Thresholds of wave heights** that can be inferred from the operational forecasts distributed by Météo-France
 - 3) Historical benchmarks of **past major events**
- => **Possibility to use the GIP with different levels of anticipation**

Level 1 : First overtopping of the seafront

Level 2 : Flooding of the buildings

Graduated Intervention Plan (GIP)	Field observations	Wave height (m) range	
Coastal flooding plan - Level 1	First wave overtopping and pebbles (or stones) projections on the waterfront (city center's parking)	> 4 m	→ Felleng
Coastal flooding plan - Level 2	Severity 1 First buildings to be flooded in the city center : School, Emergency center, town hall	6 m - 8 m	→ Bejisa Dumile
	Severity 2 Bertin street behind the lagoon, first buildings along 20 december street and the Desprez neighborhood are affected by flood	8 m - 10 m	→ Gamède
	Severity 3 Flood reaches buildings of Desprez neighborhood, inundation and flow path through Cayenne street exceeds General de Gaulle street.	> 10 m	→ Dina

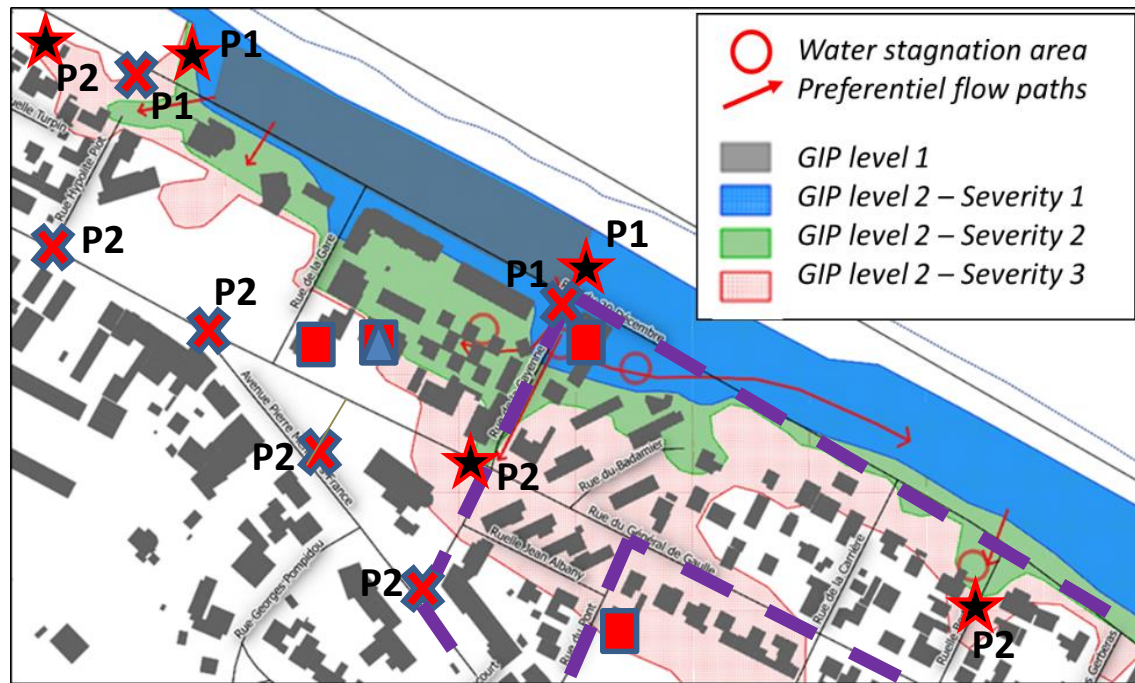

Field observations

Wave thresholds
(to compare with operational forecasts)

Historical events

Actions Plan 1 (P1) et Plan 2 (P2) : ★ Observation pts

✕ Road closure

Assets (PCS)

Shelter centers

Monitoring pathway

- > **Crisis exercise** organised in october 2017 :
- Enabled to facilitate the appropriation of the GIP
 - Enabled to **adjust the pre-determined actions**

Animation room

Crisis room

- > A method that can **easily be adapted to other territories**, scales and any marine flooding processes (overflowing and overtopping)
- > The **collaboration with the end-users** is essential
- > The constitution of a **synthetic database** enables :
 1. To conduct a robust analysis of the governing parameters
 2. To take into account the uncertainties (event duration, water levels, ...)
- > **See paper 93 on the statistical analysis of the simulation database!**

THANK YOU FOR YOUR ATTENTION!
